Universal Resource Locator (URL)

Mendel Rosenblum

Hypertext

- Text with links to other text
 - Click on links takes you somewhere else
 - Old idea:
 - Ted Nelson coined the term (early '60s), built Xanadu system
 - Doug Englebart: "Mother of all demos" in 1968
 - HyperCard for the Macintosh: 1987
- Web adapted the idea, link specification:
 - Uniform Resource Locators (URL) Provided names for web content

Parts of an URL

```
http://host.company.com:80/a/b/c.html?user=Alice&year=2008#p2
Scheme (http:): identifies protocol used to fetch the content.
Host name (//host.company.com): name of a machine to connect to.
Server's port number (80): allows multiple servers to run on the same machine.
Hierarchical portion (/a/b/c.html): used by server to find content.
Query parameters (?user=Alice&year=2008): provides additional parameters
Fragment (#p2): Have browser scroll page to fragment (html: p2 is anchor tag)
    Used on the browser only; not sent to the server.
```

URL: schemes (e.g. http)

http: is the most common scheme; it means use the HTTP protocol

https: is similar to http: except that it uses SSL encryption

file: means read a file from the local disk

mailto: means open an email program composing a message

There are several other schemes, such as ftp:, but they aren't used much anymore.

URL: Hierarchical portion (/a/b/c.html)

- Passed to the web server for interpretation. Early web servers:
 - Path name for a static HTML file.
 - Path name of a program that will generate the HTML content (e.g., foo.php).
- Web server programmed with routing information
 - Map hierarchical position to function to be performed and possibly the function's parameters
- API design, Example:
 - o /user/create
 - o /user/list
 - o /user/0x23490
 - o /user/0x23433
 - /user/delete/0x23433

Query Parameters (e.g. ?user=Alice&year=2008)

Traditionally has been to provide parameters to operation:

```
http://www.company.com/showOrder.php?order=4621047
```

For modern apps has implications of when the browser switches pages

Links

- Browser maintains a notion of current location (i.e. URL)
- Links: content in a page which, when clicked on, causes the browser to go to URL
- Links are implemented with the <a> tag:

```
<a href="http://www.company.com/news/2009.html">2009 News</a>
```

Different types of links

```
Full URL: <a href="http://www.xyz.com/news/2009.html">2009 News</a>
Absolute URL: <a href="/stock/quote.html">
    same as http://www.xyz.com/stock/quote.html
Relative URL (intra-site links): <a href="2008/March.html">
    same as http://www.xyz.com/news/2008/March.html
Define an anchor point (a position that can be referenced with # notation):
<a name="sec3">
```

CS142 Lecture Notes - URLs

Go to a different place in the same page:

Uses of URLs

- Loading a page: type the URL into your browser
- Load a image:

```
<img src="..." />
```

• Load a spreadsheet:

```
<link rel="stylesheet" type="text/css" href="...">
```

• Embedded a page:

```
<iframe src="http://www.google.com">
```

URL Encoding

What if you want to include a punctuation character in a query value?

```
http://www.stats.com/companyInfo?name=C&H Sugar
```

• Any character in a URL other than A-Z, a-z, 0-9, or any of -_.~ must be represented as %xx, where xx is the hexadecimal value of the character:

```
http://www.stats.com/companyInfo?name=C%26H%20Sugar
```

Escaping is a commonly used technique and also a source of errors

Miscellaneous Topics

Computer scientists take on hypertext:

Need to have referential integrity

The web (done by physicists):

Error 404

URI (Uniform Resource Identifier) vs. URL (Uniform Resource Locator)
